

# MOUTH TO LUNG **VS** DIRECT TO LUNG

WHAT IS THE DIFFERENCE?

Basically there are two methods a user can vape. Mouth to lung and direct to lung. Both methods provide different results for the user and will appeal to different users. Usually a mouth to lung set up will have higher resistances and lower wattage. Whereas a direct to lung is the opposite, lower resistance and higher wattages. Most new vapers will first try mouth to lung. This is closer to the way a traditional cigarette would work by drawing the vapor into your mouth first, then inhaling into your lungs. This style of vaping gives you the traditional throat hit that you would experience with smoking.

Direct to lung vaping is most common now. With this method, the vapor is inhaled directly into the lungs. The vapor usually has much more flavor and lower nicotine levels. This method also produces much more vapor due to the larger set ups.

No matter which method you use, you have made the best choice by trying to quit smoking. Keep devices on hand that can do both methods. This will keep you prepared for when you want to switch it up.
